Methods and Systems for Moving Data Objects

Background of the Invention

Field of the Invention.

The technical field of this invention is in the area of electronic data processing. More particularly, the invention relates to methods, computer program products and systems for data moving.

Description of the Related Art

Moving of data objects is well known to every user of a computer and is a standard procedure, which is routinely applied. A special application of moving data objects is the archiving process, by which data objects are moved from a first to a second storage location for safety and/or performance reasons. In enterprises, enterprise resource planning software (ERP) applications are used to control or support business processes and the management of the enterprise. ERP software is further used to manage company information of enterprises of various kinds in any field of technology by means of automatic data processing systems such as computers or computer systems. During the use of such software a huge amount of data is usually created, which contains important business information and which has to be archived from time to time.

According to the state of the art (see Helmut Stefani, Datenarchivierung mit SAP, Galileo Press GmbH, Bonn 2002, ISBN 3-89842-212-7), archiving can be performed automatically by archiving software tools, which can be

part of the ERP software. Such tools can consist of a writing module, which stores (writes) the data objects to be archived sequentially in archive files, and a deleting module, which deletes the successfully archived data from the original data object base. The writing module can select the data objects to be archived from the data base according to specific criteria, e.g. the creation time of the data. It usually does not modify the original data objects or data base. The deleting module staggeredly reads the archive file sequentially and deletes the data objects found in the archive file from the original data base. This ensures that only such data objects are deleted from the original data base, which are readably stored in the archive file. The time for the archiving procedure as a whole depends on the amount of data and varies from a few milliseconds to several hours or days. Consequently, there is in many cases a considerable time gap between writing the data into the archive file and deleting the data from the original data base. This time gap can be a reason for the following problems:

As long as the data objects are still available in the original data base, they can still be modified during said time gap. Because the deleting program does not compare the archived data object and the data object to be deleted, such modifications can be lost. This has not only the consequence of the loss of the amended data, it can additionally have the consequence that certain business processes can not be completed.

An other problem arises, if several archiving processes run in parallel. Then it can happen, that one data object is archived several times, and is no longer

unambiguously identifiable. This can have the consequence that evaluations or statistical analysis, which use the archive files, produce wrong results.

- 5 It can also happen that data objects in the original data base are read by the writing module and are simultaneously modified by an other software application. In such a case, the data can be transferred from an archiveable status to a non
- 10 archiveable status. In consequence, data objects which are not archiveable are written into the archive file and are deleted from the original data base. In effect, this can result in a loss of data.
- 15 Thus, there is a need for a method and/or data processing system providing a more efficient solution of the problems described above.

Summary of the Invention

- In accordance with the invention, as embodied and
- 20 broadly described herein, methods and systems consistent with the principles of the invention provide for moving data objects in a computer system from a first to a second storage location, comprising:
- 25 a) selecting one or more data objects from the first storage location,
- b) assigning at least one identifier (ID) of at least one type to each of the selected data objects,
- c) storing said at least one ID in a lock object,
- d) storing a data object, the at least one ID of which
- 30 is contained in the lock object, at the second storage location and assigning the second storage location to the at least on ID in the lock object,
- e) deleting a data object, the at least one ID of which

is contained in the lock object, from said first storage location,
f) deleting an at least one ID from the lock object earliest at a time at which step e) for the respective
5 data object assigned to that at least one ID has been completed.

By using this method, software applications, which require access to data objects, can check by querying
10 the lock object, whether the data to be accessed are subject to a moving process or not. If yes, the access to that data can be postponed until the moving is completed.

15 In accordance with another aspect, the invention, as embodied and broadly described herein, methods and systems consistent with the principles of the invention provide a computer system for processing data by means of or in a software application, comprising:

- 20 - memory for storing program instructions;
- input means for entering data;
- storage means for storing data;
- a processor responsive to program instructions
- programm instructions to carry out a method as of any
25 of claims 1 to 12.

The invention and its embodiments are further directed to a computer readable medium and a carrier signal comprising instructions for processing data according
30 to the inventive method and in its embodiments.

An advantage of the invention and its embodiments is that the security against data loss in data moving and archiving procedures is greatly improved. This avoids

in consequence a lot of time and money for data retrieving.

- Additional objects and advantages of the invention and its embodiments will be set forth in part in the description, or can be learned by practice of the invention. Objects and advantages will be realized and attained by means of the elements and combinations particularly pointed out in the appended claims.
- Embodiments of the invention are disclosed in the detailed description section and in the dependent and appended claims as well.

- It is understood that both the foregoing general description and the following detailed description are exemplary and explanatory only and are not restrictive of the invention and its embodiments, as claimed.

Brief Description of the Drawings

- The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate examples of embodiments of the invention and, together with the description, explain the principles of the invention. In the drawings,

- Fig. 1 is a schematic block diagram of the implementation of the inventive method within a computer system.

- Fig. 2 is a schematic diagram of an exemplary structure of a data object in accordance with the principles of the inventive method.

Fig. 3 is an exemplary flow diagram of an implementation of the selecting module shown in Fig. 1.

Fig. 9 shows an example of a flow chart for a software module by means of which the locks can be deleted.

Detailed Description

25 Computer system and program are closely related. As used hereinafter, phrases, such as "the computer provides" and "the program provides or performs specific actions", "a user performs a specific action" are convenient abbreviation to express actions by a
30 computer system that is controlled by a program or to express that the program or program module is designed to enable the computer system to perform the specific

action or the enable a user to perform the specific action by means of a computer system.

Reference will now be made in detail to the principles of the invention by explaining the invention on the basis of an archiving process, examples of which are illustrated in the accompanying drawings. Examples, mentioned therein, are intended to explain the invention and not to limit the invention in any kind.

Within the concept of this description, the terms used shall have their usual meaning in the context of the field of data processing unless defined otherwise in the following section:

A computer system can be a stand alone computer such as a PC or a laptop or a series of computers connected as a network, e.g. a network within a company, or a series of computers connected via the internet. A data object to be archived can be any kind or type of data, e.g. numerical or textual data, image data, meta data, irrespective whether the data are implemented as whole files or parts of files or fields in tables, irrespective whether they are stored in volatile memory or nonvolatile memory. As an example, data objects according to the present invention can be implemented as one or more fields of one or more tables, particularly of tables of a relational data base system, or as objects in an object orientated programming language.

The term ERP software shall be considered to comprise any software application that supports the business processes of an enterprise.

A storage location is volatile or nonvolatile storage means accessible by the computer system. It can be any kind of computer storage means known to one of ordinary skill, e.g. RAM, magnetical or optical storage, such as floppy disk, hard disk, MO-Disk, CD-ROM, CD RW, DVD ROM, DVD RW, etc. The first and second storage location can be identical. In this case, the archived data objects have to be stored at a place different to the place of the original data objects to be archived. The second storage location can also be implemented as a file, located anywhere in the accessible nonvolatile storage means. Such file is subsequently referred to as archive file.

An identifier (ID) is a type of data, which allows an unambiguous identification of the data object to be archived, it can be implemented for example as a number or a combination of alphanumerical characters or as a characteristic part of the data object to be archived. It is clear from that definition that a data object can have a wide variety of IDs. A lock object is a data object, in which the identifiers are stored. It can be implemented e.g. as a file on a storage means or as a data array in computer memory. A first lock object is stored advantageously in a nonvolatile storage means and a second lock object is stored in volatile and/or nonvolatile storage means.

The assignment of the second storage location to an ID can be implemented by a table, in which one field of a line contains the ID and another field of that line contains a link to the second storage location, e.g. a file name. This table can be stored as a file on a nonvolatile storage means.

Fig. 1 depicts one example of an implementation of a first embodiment of the invention. Fig. 1 shows a computer system 101 comprising a computer 103 having a CPU 105, a working storage 112, in which an ERP software 111 is stored for being processed by CPU 105. ERP software 111 comprises program modules 106, 109, 110 for carrying out the inventive data archiving process. Computer System 101 further comprises input means 113, output means 112 for interaction with a user, and general input/output means 104, including a net connection 114, for sending and receiving data. A plurality of computer systems 101 can be connected via the net connection 114 in the form of a network 113. In this case the network computers 113 can be used as further input/output means, including as further storage locations. Computer system 103 further comprises a first storage means 107, in which data to be archived and the lock object are stored, and a second storage means 108, in which the archived data are stored.

In case the program modules 106, 109, 110 are processed by CPU 105 in order to carry out the inventive process, one or more data objects stored in the first storage means 107 are selected by selection module 110. Selection module 110 assigns an ID to each of the selected data objects and stores the ID in the lock object at the storage location 107. Writing module 106 reads the data objects and the lock object and stores such data objects, the ID of which are contained in the lock object to the second storage location 108. Additionally, the second storage location 108 is assigned to the respective ID of the data object in the lock object. Deleting module 109 then reads the archived data objects in the second storage location

108 and deletes the data objects, which it could
successfully read from the original set of data objects
in the first storage location 107. After deleting a
specific data object, to which an ID was assigned, that
5 ID is deleted from the lock object.

In an alternative embodiment, the lock object is
created by the selection module and not by the writing
module.

10

In a second implementation of the invention, a data
object to be archived comprises one or more fields of
one or more tables, and the ID of the respective object
comprises one or more key fields of that data object.
15 This can best be seen from Fig. 2. In this instance,
various sets of data objects are created in the form of
two-dimensional data arrays, i.e. two tables having
columns named field A to field X and field Y,
respectively, and a certain, unspecified number of
20 lines. A field of the array or table is defined by the
name of the column and the respective line. Such field
can contain data to be archived. It can alternatively
contain a reference to a line of a further table. For
example, in table 1 field X in line 2 contains a
25 reference to line 3 in table 2. A data object to be
archived comprises fields of one line of the respective
table. If one of the fields contains a reference to a
line of an other table, fields of this referenced line
belong to the data object, too. In the example in Fig.
30 2, a data object to be archived comprises the fields of
line 2 in table 1 and fields of line 3 in table 2.
An ID of such a data object can be implemented by the
content of one or more so-called key fields, if the
combination of these key fields is unique within the
35 respective table. In the example, the fields of "field

A" and "field B" can be used as key fields for table 1, whereas field A alone is key field in table 2. Within this example, assigning an ID to the data object means to use the content of the fields of columns field A and B of the respective lines as the ID for that particular line. In line with this assignment, the IDs for the data object to be archived are stored as a first type ID in a first type lock object named persistent lock object in Fig. 2 and as a second type ID in a second type lock object named transactional lock object. The persistent lock object is implemented as a table having two columns, the first of which contains the first type ID 1. The second type ID, ID 2, can be implemented as a one-dimensional data array stored in the working memory of the computer system. However, it can be implemented as a file on a nonvolatile storage means, too. The first type ID, ID 1, is deleted after the selected data object has been deleted according to step e) of the inventive process, and the second type ID, ID 2, is deleted immediately after the time as defined in step f). Alternatively, type ID 1 IDs can be deleted after all the selected data objects have been deleted according to step e). As can be seen, both ID types have identical content, the ID of the respective lines of the data to be archived. However, this is not a necessary condition. It can be seen from the fact that the ID 2 of line BB is deleted, that this line has already been archived, whereas line BC has not yet been stored to the archive file. The two types can also be stored together in one lock object. The persistent lock objects further contain a column by which a filename is assigned to the ID of the data object, i.e. that data object to be archived. In the example, line 1 is archived in a file named 001, lines 2 and 3 in file 002, and line 4 in file 003.

The selection of the data object can be implemented by an automatic procedure, such as by a simple query, that returns all lines having a certain field that satisfies a certain condition. For example, the procedure could return all lines in which the content of a date field pre-dates or post-dates a certain deadline. Selection can also be implemented by a user to whom a selection table is presented via a graphical user interface.

10

A further embodiment is characterized in that in step c) the IDs of the second type are stored in a second lock object immediately after performing step b) for the respective data object. Alternatively, in step c) the second type of ID of the selected data object is stored shortly before the storing process according to step d) for the data object assigned to that ID is started.

15

20 A further embodiment, is characterized in that in step c) the IDs of the first type of all selected data objects are stored before the first storing process according to step d) is started.

25 In a further embodiment the invention comprises g) checking before or while performing any of steps a) to c) for a data object, whether an ID for that data object has been stored in a lock object, and if yes, skipping at least step d) for that data object.

30

Additionally, the invention comprises h) checking before or while performing any of steps a) to d) for a data object, whether the data object is contained in the second storage location, and if yes, skipping at least step d) for that data object.

35

Another embodiment is characterized by said checking is performed by querying a lock object.

- 5 In yet another embodiment, the step d) checking comprises checking whether the data object assigned to the respective ID has been completely stored in the second location and, in case of no, skipping at least steps e) and f) for that data object and deleting the
10 ID from the lock object.

The invention is now described in more detail with reference to Figs. 3 to 5, which are schematic flow diagrams of exemplary implementations of the selecting,
15 writing and deleting modules, respectively, as shown in Fig. 1. Within the context of this description, and particularly the Figs. 3 to 9, a first type ID is called a P-lock (permanent) and a second type ID is called a T-lock (transactional). So, setting a P- or T-
20 lock for a selected object means to store an ID of that object in a respective lock object. The term "permanent" results for the property of the P-lock of existing permanently, as long as the data object is not yet deleted from its original storage location. The
25 term "transactional" results from the property of the T-lock of existing only as long as a specific action (e.g. checking of archiveability) is performed on a selected data object or, in other words, of being deleted shortly after the respective action has been
30 performed.

In the flow chart of the selecting module in Fig. 3, a data object is selected in a first step 301. Subsequently, a T-lock is set on this object in step
35 302. If the T-lock was successfully set (step 303),

that is, if it did not yet exist, it is checked in step 304 whether a P-lock already exists in the selected data object. If not, the next data object is selected in step 309. The setting of the T-lock (step 302) and the check (step 303) whether it is successfully set can advantageously be implemented as one "atomic" step. This means that both steps can be executed essentially at the same time or, in other words, the time gap between both can be essentially zero.

10

Both checks (steps 303 and 304) can also be implemented by querying the respective lock objects.

If a P-lock exists, the T-lock is deleted (step 308) and the next data object is selected (step 309). If no

15

P-lock exists, it is checked in steps 305 and 306, whether the data object is archiveable. Such checking comprises a test whether the data in the data object is readable, complete, not fraught with obvious failures etc. If the test is successful, a P-lock is set on that data object in step 307, whereby no archive file is assigned to the data object at that point. Then the T-lock is deleted (step 308) and the next data object is selected (step 309).

20

25 In the flow chart of the writing module in Fig. 4, a data object is selected in a first step 401.

Subsequently, a T-lock is set on this object in step 402. If the T-lock was successfully set (step 403), it is checked in step 404 whether a P-lock already exists in the selected data object, whereby no file must be assigned to that data object at that point of the process. If the condition is not fulfilled, the T-lock is deleted in step 407, and the next data object is selected in step 408. If a P-lock exists, the data

30

35 object is stored in an archive file in step 405 and the

archive file is assigned to the data object in step 406, e.g. by adding the file name to the lock object as shown in Fig. 2. Subsequently, the T-lock is deleted (step 407), and the next data object is selected (step 5 408).

In the flow chart of the deleting module in Fig. 5, a data object that has already been archived is selected (step 501). This can be implemented by checking the 10 archive files. If a data object has been selected and successfully read from the archive file, that data object is deleted from the original storage location (step 502), the P-lock is deleted (step 503), and the next data object is selected (step 504).

15 In the exemplary flow chart of a further exemplary implementation in Fig. 6, the selecting and writing module described above are combined to one module. Accordingly, a data object is selected in a first step 20 601. Subsequently, a T-lock is set on this object in step 602. If the T-lock was successfully set (step 603), it is checked in step 604 whether a P-lock already exists in the selected data object. If not, the next data object is selected (step 610). If a P-lock 25 exists on that object, the T-lock is deleted (step 609) and the next data object is selected (step 610). If no P-lock exists on that object, it is checked in step 605, whether the data object is archiveable. If this check fails (step 606), the T-lock is deleted (step 30 609), and the next data object is selected (step 610). If the check is positive, the data object is stored (step 605) in an archive file, a P-lock is set (step 608) with the archive file assigned, the T-lock is deleted (step 609) and the next data object is selected 35 (step 610).

Fig. 7 shows by way of an exemplary flow chart how any software application can use the concept of the P- and T-locks to ensure that the measures, the software application is going to apply on the data object, do not influence the archiving process. A software application that is programmed to have a read and/or write access to data objects, which can be subject of an archiving process as described, comprises the following steps as shown in Fig. 7. In a first step 701, the data object is selected. Then a T-lock is set in step 702 on that object by the application. If the T-lock is successfully set (step 703), it is checked in step 704, whether a P-lock exists on that object, otherwise the application terminates in step 707. If a P-lock exists on that object (step 704), the T-lock is deleted (step 706), and the application terminates (step 707). If no P-lock exists, i.e. the data object is not subject to an archiving process, the application can have read/write access to the data object in a working step 705. Subsequently the application deletes the T-lock (step 706) and terminates (step 707).

Fig. 8 shows a process alternative to that shown in Fig. 7, including a conditional deletion of a P-lock. In a first step 801, the data object is selected. Then a T-lock is set on that object by the application (step 802). If the T-lock is successfully set (step 803), it is checked (step 804), whether a P-lock exists on that object, otherwise the application terminates (step 809). If no P-lock exists (step 804), i.e. the data object is not subject to an archiving process, the application can have read/write access to the data object in working step 807. Subsequently, the application deletes the T-lock (step 808) and

- terminates (step 809). If a P-lock exists (step 804), it is checked (step 805), whether a file is assigned to it. If a file is assigned, the application deletes the T-lock (step 808) and terminates (step 809). If no file is assigned, the P-lock is deleted (step 806), and the application can have read/write access to the data object (step 807). Subsequently, the application deletes the T-lock (step 808) and terminates (step 809).
- 10 This procedure is particularly useful, in that data objects, which are not yet stored in an archive file, can be still altered. Consequently, they can be archived only at the next archive run.
- 15 Fig. 9 shows an example of a flow chart for a software module by means of which the locks set by the modules described above can be deleted. This can be useful in cases in which no archive files are assigned to P-locks or in which P-locks have been deleted for a user.
- 20 Therein, a P-lock is nothing else than a data object and can be treated in the same way as described above. In a first step 901, a P-lock is selected. Then a T-lock is set to the P-lock in (step 902). If the T-lock is successfully set (step 903), it is checked (step 904), whether the P-lock has a file assigned. If the T-lock is not set successfully, the module terminates (step 907). If the selected P-lock has no file assigned (step 904), the P-lock is deleted (step 905). Then the T-lock is deleted (step 906) and the module terminates (step 907). Alternative to the termination step 907, a next P-lock can be selected.
- 30

Modifications and adaptations of the present invention will be apparent to those skilled in the art from
35 consideration of the specification and practice of the

invention disclosed herein. The foregoing description of an implementation of the invention has been presented for purposes of illustration and description. It is not exhaustive and does not limit the invention to the precise form disclosed. Modifications and variations are possible in light of the above teachings or can be acquired from the practicing of the invention. For example, the described implementation includes software, but systems and methods consistent with the present invention can be implemented as a combination of hardware and software or in hardware alone. Additionally, although aspects of the present invention are described for being stored in memory, one skilled in the art will appreciate that these aspects can also be stored on other types of computer-readable media, such as secondary storage devices, for example, hard disks, floppy disks, or CD-ROM; the Internet or other propagation medium; or other forms of RAM or ROM. It is intended that the specification and examples be considered as exemplary only, with a true scope and spirit of the invention being indicated by the following claims.

Computer programs based on the written description and flow charts of this invention are within the skill of an experienced developer. The various programs or program modules can be created using any of the techniques known to one skilled in the art or can be designed in connection with existing software. For example, programs or program modules can be designed in or by means of ® Java, C++, HTML, XML, or HTML with included Java applets or in SAP R/3 or ABAP.

What is claimed is:

1. A method for moving data objects in a computer system from a first to a second storage location, comprising:
 - 5 a) selecting one or more data objects from the first storage location,
 - b) assigning at least one identifier (ID) of at least one type to each of the selected data objects,
 - 10 c) storing said at least one ID in a lock object,
 - d) storing a data object, the at least one ID of which is contained in the lock object, at the second storage location and assigning the second storage location to the at least one ID in the lock object,
 - 15 e) deleting a data object, the at least one ID of which is contained in the lock object, from said first storage location,
 - f) deleting an at least one ID from the lock object earliest at a time at which step e) for the
20 respective data object assigned to that at least one ID has been completed.
2. The method of claim 1, wherein a data object comprises one or more fields of one
25 or more tables and wherein the at least one ID comprises one or more key fields of the one or more tables.
3. The method of claim 1 or 2, wherein
30 in step d) the data objects are stored in one or more files and wherein an assignment of the at least one ID to a filename or file, in which the data object assigned to the at least one ID is to be stored, is stored in the lock object.

4. The method of one of claims 1 to 3, wherein
IDs of at least two types are stored in one or more
lock objects, a first type, the IDs of which are
deleted from the respective lock object after the
respective data object has been deleted according
to step e), and a second type, the IDs of which are
deleted from the respective lock object after
completion of step c) for a particular first type
ID.
5. The method of claim 4, wherein
in step c) the IDs of the second type are stored in
a second lock object immediately after performing
step b) for the respective data object.
6. The method of claim 4, wherein
in step c) the second type of ID of the selected
data object is stored shortly before the storing
process according to step d) for the data object
assigned to that ID is started.
7. The method of one of claims 4 to 6, wherein
in step c) the IDs of the first type of all
selected data objects are stored before the first
storing process according to step d) is started.
8. The method one of claims 1 to 7, further
comprising:
g) checking before or while performing any of steps
a) to c) for a data object, whether an ID for that
data object has been stored in a lock object, and
if yes, skipping at least step d) for that data
object.
9. The method of one of claims 1 to 8, further
comprising:
h) checking before or while performing any of steps

a) to d) for a data object, whether the data object is contained in the second storage location, and if yes, skipping at least step d) for that data object.

- 5 10. The method of claim 9, wherein
said checking is performed by querying a lock
object.
11. The method of one of claims 1 to 10, further
comprising:
- 10 i) in case of a failure in step d) checking,
whether the data object assigned to the respective
ID has been completely stored in the second storage
location, and in case of no, skipping at least
steps e) and f) for that data object and deleting
15 the ID from the lock object.
12. The method of one of claims 1 to 11
for use in an enterprise resource planning
software.
13. A computer system for processing data by means of
20 or in a software application, comprising:
- memory for storing program instructions;
 - input means for entering data;
 - storage means for storing data;
 - a processor responsive to program instructions
 - 25 - programm instructions to carry out a method as of
any of claims 1 to 12.
14. A computer program comprising program code means
for performing a method as of any of claims 1 to 12
if said program is executed on a computer system.
- 30 15. A computer readable medium comprising program code
for performing a method as of any of claims 1 to 12

if said program code is executed on a computer system.

16. A computer program product comprising a computer readable medium according to claim 15.

- 5 17. A computer data signal embodied in a carrier wave comprising:
program code for performing a method as of any of
claims 1 to 12 if said program code is executed on
a computer system.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ BLACK BORDERS
- ☐ IMAGE CUT OFF AT TOP, BOTTOM OR SIDES
- ☒ FADED TEXT OR DRAWING
- ☐ BLURRED OR ILLEGIBLE TEXT OR DRAWING
- ☐ SKEWED/SLANTED IMAGES
- ☐ COLOR OR BLACK AND WHITE PHOTOGRAPHS
- ☐ GRAY SCALE DOCUMENTS
- ☐ LINES OR MARKS ON ORIGINAL DOCUMENT
- ☐ REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY
- ☐ OTHER: _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
